

Radiological Report : MRI Head :

Axial T2 and proton density, sagittal T2, coronal T1 and FLAIR and axial T2* gradient echo imaging.

There are shallow bilateral subdural collections, each measuring approximately 9mm in maximum depth, and overlying the frontal and parietal lobes. There is further blood overlying the tentorium cerebelli.

A few scattered high signal foci are noted in keeping with a degree of ischaemic small vessel disease. A few tiny foci of haemosiderin deposition are noted in the right subdural collection, and the left collection anteriorly.

Overall the subdural collections are of water signal. There is some mass effect with mild effacement of the sulci, but no other significant abnormality.

COMMENT: Bilateral chronic subdural haematomas with mild mass effect.
